FOR: SYSTEM AND METHOD FOR
AUTOMATICALLY GENERATING PROGRAM

DOCKET NO.: KUD.041

SYSTEM AND METHOD FOR AUTOMATICALLY GENERATING PROGRAM

Background of the Invention

1. Field of the Invention

5   The present invention relates to automatic creation of a program. More particularly, the present invention relates to a system and method for automatically creating a program such as a software component and a client program using this component.

10 ### 2. Description of the Related Art

        ActiveX pronounced by Microsoft Corporation makes it easy to achieve a distributed computer system and division of software into components, under a Windows-based network environment. In conjunction

15 with it, the automatic creation of a component has been recently tried.

        As this type of a conventional technique, there is COMTI available from Microsoft Corporation, which creates an ActiveX component to access to a

20 mainframe. However, although COMTI can create the component for accessing to the mainframe, COMTI cannot create a client program using the created component. For this reason, a program developer needs to develop the client program separately and manually on the

25 basis of the opened or released data of the created components.

        As another conventional example of a

technique for automatically creating a component, a system and method for creating an object oriented database operation program is disclosed in Japanese Laid Open Patent Application (JP-A-Heisei 11-224184).

5 In this reference, a schema data defined in an object oriented database is acquired, a program for an automation server (code component) is automatically created for an automation communication based on the acquired schema data and a program template file, and

10 a client program serving as an external application is automatically created using a schema class of a database opened by this automation server, and its attribute and its method at the same time.

If the client program using the created

15 components is separated from the creation of the components and separately and manually developed, this imposes a large burden on the developer of the client program, such as the increase in the number of work steps. Also, the development of the client program is

20 decelerated in the worst case.

Problems in the conventional technique will be described by taking as an example, the creation of software components having a function of accessing to a transaction process program running on a mainframe

25 and a client program using the same.

As shown in Fig. 1A, the access to a transaction process program 301 running on a mainframe

(for example, ACOS2/4/6 available from NEC) 300 has been conventionally executed from a private online terminal 302 such as ETOS52G. Fig. 1B shows an example of an operational procedure from the private

5   online terminal 302 to the transaction process program 301. In this example, a message is sent to the transaction process program 301 on the mainframe 300 from the private online terminal 302 in an order of a message "M1", a message "M2" and a message "M3".

10   Accordingly, the transaction process program 301 executes a series of sequences. In the messages "M1" to "M3", several parameters "PR1" to "PR3" are specified as necessary. The individual parameter has any one of an input parameter, an output parameter, an

15   input/output parameter and no operation. Its state is dynamically changed on the basis of a message ID among the messages "M1" to "M3".

     If the access function to the transaction process program on such a mainframe is enabled from a

20   Windows-based general personal computer other than the private online terminal, a software component 303 is created in which methods "MT1" to "MT3" respectively corresponding to the messages "M1" to "M3" are installed as shown in Fig. 1C, and also a client

25   program 304 is created using the same. In the conventional technique, the software component 303 is automatically created from various definition data

necessary to create the software component. The
client program 304 is created separately and manually
by a developer of the client program based on the
opened or released data of the created software
5 component.

In this case, as a problem, the order of
starting the methods "MT1" to "MT3" is not known even
if the opened or released data of the created software
component 303 is viewed. Thus, it is not easy for the
10 developer of the client program 304 to prepare the
description of the order of calling the methods "MT1"
to "MT3". In order to understand the order of
starting the methods "MT1" to "MT3", it is necessary
to know that the method "MT1" corresponds to the
15 message "M1", the method "MT2" corresponds to the
message "M2", and the method "MT3" corresponds to the
message "M3", respectively, and that the transmission
of the messages in the order of the messages "M1" to
"M3" is required in the specification of the
20 transaction process program 301 on the mainframe 300.
For these purposes, both of knowledge with regard to
the component and knowledge with regard to a
transaction process in a mainframe are required.
Usually, the developer of the client program, although
25 having the knowledge of the component, does not have
the knowledge of the mainframe.

As another problem, although data about the

type of each of the parameters of the methods "MT1" to

"MT3" can be known from their opened or released data,

the state of the individual parameter is unknown among

the states of the input parameter, the output

5   parameter, the input/output parameter and the no

operation. Thus, it is not easy for the developer of

the client program 304 to prepare the description of a

process for setting a value for a parameter required

before and after calling the methods "MT1" to "MT3" in

10 the client program 304, and a process for acquiring

the value from the parameter. For example, if the

parameter "PR1" is the input parameter, it is

necessary to describe the process for setting the

value to the parameter "PR1" before calling the method

15 "MT1". In a case of the output parameter, it is

necessary to describe the process for acquiring the

value of the parameter "PR1" after calling the method

"MT1". In a case of the input/output parameter, it is

necessary to describe the process for setting the

20 value to the parameter "PR1" before calling the method

"MT1", and it is also necessary to describe the

process for acquiring the value of the parameter "PR1"

after calling. In order to understand the type of

such a parameter, it is necessary to have the

25 knowledge with regard to the treatment of the

parameters in the transaction process in the mainframe

300, in addition to the knowledge with regard to the

component, similarly to the case of understanding the
order of actuating the methods "MT1" to "MT3".

The developer of the client program 304 may
inquire of a technician for the mainframe 300 about
5 the definition of the order of starting the methods
"MT1" to "MT3" and about the types of the respective
parameters. However, because of the completion of the
development of the software component, there may be a
case that the technician for the mainframe 300 having
10 relation to the development of the software component
does not exist at that time, and the inquiry is
impossible. Even in the case of the existence of the
technician, the inquiry itself is trouble for both the
developer and the technician. Moreover, when the
15 developer inquires of another mainframe technician
about them, the technician having no relation to the
development of the software component does not
understand the component, even if knowing which
parameter is responsible for the input or the output,
20 or even if knowing the order of sending out the
messages. Thus, it is difficult to carry out the
explanation so that the developer of the client
program can understand.

On the other hand, Japanese Laid Open Patent
25 Application (JP-A-Heisei 11-224184) discloses a
technique for automatically creating a client program
serving as an external application using a schema

class of a database published by an automation server, which is automatically created, and its attribute and its method. However, the client program disclosed therein is the interface to access to the database.

5 This is originally data corresponding to a C^{++} class at a stage of the development of an object oriented database, and it does not require to a client side the concepts of an calling order (sequence), an input, an output and an input/output. Thus, the technique

10 disclosed therein cannot solve the above-mentioned problems of the conventional technique.

In conjunction with the above description, a code generating apparatus in an application field of a distributed object system is disclosed in Japanese

15 Laid Open Patent application (JP-A-Heisei 10-111802). This reference is related to a method which is implemented in a computer which is on a network and automatically assembles an object independent on language to generate a network application used for a

20 distributed object system. The method is composed of a step of receiving schematic representation of the network application, and the schema representation defines a plurality of links among distributed object representations. The method is further composed of a

25 step of loading the schematic representation of the network application in a symbol table, and storing a portion of the schematic representation in the symbol

table as a plurality of entries. The method is
further composed of a step of determining a least one
program source file which should be generated and at
least one corresponding program template which should
5   be used, and the program template contains references
to the plurality of entries in the symbol table. The
method is further composed of a step of combining the
plurality of entries in the symbol table with at least
one corresponding program template, which are compiled
10   thereby, and generating at least one program source
file suitable for the portion of the network
application.

Summary of the Invention

15   Therefore, an object of the present invention
is to provide an automatic program creating system and
method in which software components and a client
program using the same are created.

Another object of the present invention is to
20   provide an automatic program creating system and
method in which there are stored only data necessary
to create software components to access to a
transaction process program running on a mainframe,
but also a definition data containing data necessary
25   to create a client program using the software
components, and automatically create a source code of
the client program based on this definition data.

Still another aspect of the present invention is to provide an automatic program creating system and method in which load of a developer of the client program can be largely reduced.

5   In an aspect of the present invention, an automatic software component creating system includes a software component definition data storage section which stores software component definition data therein, a software component creation rule storage

10   section which stores software component creation rules therein, and a client program creation rule storage section which stores client program creation rules therein. A software component creating section creates a software component module with one or more

15   software components based on the software component definition data and the software component creation rules in response to a start instruction. A client program creating section creates a client program source code based on the software component definition

20   data, the software component module, and the client program creation rules, when the software component module is created.

Here, the software component definition data includes one module data which includes at least one

25   component data, which includes at least one method data, which includes at least one parameter data. In this case, it is desirable that the module data has a

module name, the component data has component data and

component attribute data, the method data has a method

name, method attribute data, method call format data,

and method call order data, and the parameter data has

5 a parameter name, a parameter type, and a parameter

type data.

Also, the automatic software component

creating system may further include a software

component defining section which defines the software

10 component definition data from inputted data to store

in the software component definition data storage

section. In this case, the software component

defining section may include a component data defining

section, a method data defining section and a

15 parameter data defining section. The component data

defining section defines the component data associated

with the module data from the inputted data. The

method data defining section defines the method data

associated with the component data from the inputted

20 data. The parameter data defining section defines the

parameter data associated with the method data from

the inputted data.

Also, the software component creating section

may include a parameter creating section, a method

25 creating section, a component creating section, and a

module creating section. The parameter creating

section creates parameter(s) from the software

component definition data and parameter creation rules

in response to a parameter creation request. The

method creating section generates the parameter

creation request which creating method(s) from the

5   software component definition data and method creation

rules in response to a method creation request. The

component creating section generates the method

creation request while creating component(s) from

software component definition data and component

10 creation rules in response to a component creation

request. The module creating section generates the

component creation request while creating the software

component module from the software component

definition data and module creation rules.

15   In this case, the software component creation

rules may include module creation rules, the component

creation rules, the method creation rules, and the

parameter creation rules. In each of the module

creation rules, a rule for creation of a project file

20 of the module is described. The component creation

rules includes component framework creation rules in

each of which a rule for creation of a framework of

the component is described, property creation rules in

each of which a rule for creation of property of the

25 component is described, and initial value creating

rules, in each of which initial values to be set in

the property are described. The method creation rules

includes method framework creation rules in each of
which a rule for creation of a framework of the method
is described, and method logic creation rules in each
of which logic to be executed by the method is

5   described. In each of the parameter creation rules,
it is described that a parameter name and a type of
parameter are linked.

Also, the client program source code creating
section may include a parameter definition creating

10 section, a pre-process creating section, a component
call creating section, a post-process creating section
and a client module creating section. The parameter
definition creating section creates declaration and
definition of each of the parameters corresponding to

15 a method to be called from a client program from the
software component definition data and parameter
definition creation rules of the client program
creation rules in response to a parameter definition
creation request. The pre-process creating section

20 creates a pre-process which needs to be executed prior
to a call of the software component based on the
software component definition data and pre-process
creation rules of the client program creation rules in
response to a pre-process creation request. The

25 component call creating section creates a call process
of each of the methods of the software component based
on the software component definition data and

component call creation rules of the client program

creation rules in response to a component call

creation request. The post-process creating section

creates a post-process, which needs to be executed

5 after the call of the software component based on the

software component definition data and post-process

creation rules of the client program creation rules in

response to a post-process creation request. The

client module creating section creates a framework of

10 the client program source code based on the software

component definition data and client module creation

rules of the client program creation rules while

respectively outputting the parameter definition

creation request, the pre-process creation request,

15 the component call creation request and the post-

process creation request to the parameter definition

creating section, the pre-process creating section,

the component call creating section, and the post-

process creating section.

20   In another aspect of the present invention,

an automatic software component creating method is

attained by (a) creating a software component module

with one or more software components based on software

component definition data and software component

25 creation rules in response to a start instruction; and

by (b) creating a client program source code based on

the software component definition data, the software

component module, and client program creation rules,

when the software component module is created.

Here, the software component definition data

includes one module data which includes at least one

5   component data, which includes at least one method

data, which includes at least one parameter data.

Also, the module data has a module name, the component

data has component data and component attribute data,

the method data has a method name, method attribute

10   data, method call format data, and method call order

data, and the parameter data has a parameter name, a

parameter type, and a parameter type data.

Also, the automatic software component

creating method may include the step of (c) defining

15   the software component definition data from inputted

data.   In this case, the (c) defining step may be

attained by defining the component data associated

with the module data from the inputted data; by

defining the method data associated with the component

20   data from the inputted data; and by defining the

parameter data associated with the method data from

the inputted data.

Also, the (a) creating step may be attained

by (d) generating a component creation request while

25   creating the software component module from the

software component definition data and module creation

rules of the software component creation rules; by (e)

generating a method creation request while creating

component(s) from software component definition data

and component creation rules of the software component

creation rules in response to the component creation

5   request; by (f) generating a parameter creation

request which creating method(s) from the software

component definition data and method creation rules of

the software component creation rules in response to

the method creation request; and by (g) creating

10   parameter(s) from the software component definition

data and parameter creation rules in response to the

parameter creation request.

           Also, the (b) creating step may be attained

by (h) creating declaration and definition of each of

15   the parameters corresponding to the method to be

called from a client program from the software

component definition data and parameter definition

creation rules of the client program creation rules in

response to a parameter definition creation request;

20   by (i) creating a pre-process which needs to be

executed prior to a call of the software component

based on the software component definition data and

pre-process creation rules of the client program

creation rules in response to a pre-process creation

25   request; by (j) creating a call process of each of the

methods of the software component based on the

software component definition data and component call

creation rules of the client program creation rules in

response to a component call creation request; by (k)

creating a post-process, which needs to be executed

after the call of the software component based on the

5 software component definition data and post-process

creation rules of the client program creation rules in

response to a post-process creation request; and by

(l) creating a framework of the client program source

code based on the software component definition data

10 and client module creation rules of the client program

creation rules while generating the parameter

definition creation request, the pre-process creation

request, the component call creation request and the

post-process creation request.

Description of the Preferred Embodiment

Hereinafter, an automatic program creating
20   system of the present invention will be described below in detail with reference to the attached drawings.

Fig. 2 is a block diagram showing the structure of the automatic program creating system
25   according to the first embodiment of the present invention. With reference to Fig. 2, a system for automatically creating a program in the first

embodiment has a software component defining section 20 for creating software component definition data 50 based on data inputted from an input/output unit 200 by a user. In order to allow not only the creation of

5   software components but also the creation of a client program, the software component defining section 20 can simultaneously define not only data necessary to create the software components as the definition data, but also definition data 51 necessary to create the

10 client program. Also, the definition data 51 necessary to create the client program can be added to the already stored definition data.

As an example of the definition data 51 necessary to create the client program, there is a

15 data of a method call order. Also, as another example, there is a data to define each parameter in the methods, as any one of an input parameter, an output parameter, an input/output parameter and no operation.

The system for automatically creating a

20 program according to the first embodiment has two program creating sections such as an automatic software component creating section 30 and an automatic client program creating section 40. The automatic software component creating section 30

25 automatically creates a software component module 70 based on the definition data of the software component definition data 50 in response to a start instruction

from a user input/output apparatus 200. On the other
hand, the automatic client program creating section 40
automatically creates a source code 90 of the client
program for the software component module 70, by using
5 the data 51 necessary to create the client program
included in the software component definition data 50,
when the software component module 70 is created.

The automatic client program creating section
40 is provided with a definition data extracting
10 section 41, a client module creating section 42, a
parameter definition creating section 43, a pre-
process creating section 44, a component call creating
section 45 and a post-process creating section 46.

The definition data extracting section 41
15 extracts a definition data necessary to create a
client program from the software component definition
data 50.

The client module creating section 42 creates
the frame of an entire module based on the extracted
20 definition data. Then, the parameter definition
creating section 43 creates within the frame, the
declarations of variables used as the parameters for
an input, an output and an input/output, and a process
for initializing the parameters.

25   The pre-process creating section 44 creates
the declaration of the component, the input parameter
necessary before calling the component, and a process

for setting values for properties.

The component call creating section 45 creates processes for calling methods.

The post-process creating section 46 creates

5   the processes required after calling the component such as processes for acquiring values of the output parameters. In this way, the source code 90 of the client program is created.

The characteristic description is exemplified

10 in the source code 90 of the client program in Fig. 2. A portion for a symbol 91 denotes a description of method call processes which are automatically created by the component call creating section 45 based on the definition data 51 necessary to create the client

15 program in the software component definition data 50. This example is described so as to call the methods in an order of a connection method, a transmission method, a reception method and a disconnection method based on the definition data indicating that the methods must

20 be called in an order of connection, transmission, reception and disconnection.

A portion for a symbol 92 denotes a description of processes for setting values for parameters, and the description of the processes is

25 automatically created by the pre-process creating section 44 based on the types of the parameters of the method. From the description of [Parameter1=?] and

[Parameter2=?] (Parameter1 and Parameter2 are the names of the parameters), a developer of the client program can easily recognize that the parameters are input parameters and that the values need to be set

5   before calling a method. Here, the data of an actual input source (for example, the data about a predetermined input column in GUI) is later set for the portion [?] by a manual operation. At this time, if the name of the parameter is defined as a name

10 having a proper meaning, an operation to check the usage of a component can be minimized.

A portion for a symbol 93 denotes a description of processes for acquiring values of parameters, and the description of processes is

15 automatically created by the post-process creating section 46 based on the type data of the parameter of the method. From the description of [Parameter3=?] and [Parameter4=?], the developer of the client program can easily recognize that the parameters are

20 output parameters and that values need to be acquired after calling a method. Here, the data of an actual output destination (for example, the data about a predetermined output column in GUI) is later set for the portion [?] by a manual operation. At this time,

25 if the name of the parameter is defined as a name having a proper meaning, an operation to check usage of a component can be minimized.

The source code 90 of the client program automatically created by the automatic client program creating section 40 serves as a sample (template) when the developer of the client program develops the

5 client program using the software component module 70 created by the automatic software component creating section 30. The developer completes the non-defined portions (for example, the portions "?" in the symbols 92, 93) in the source code 90 of the automatically

10 created client program, and prepares the GUI portion of the client program by using Visual Basic, as necessary, and then completes the source code 90 of the client program.

With reference to Fig. 3, the system for

15 automatically creating a program according to the first embodiment of the present invention includes a processor 10, a memory 100 and a user input/output unit 200 as a main body. The user input/output unit 200 is composed of an input unit such as a keyboard

20 and a mouth, and a display such as LCD. The memory 100 is formed of a semiconductor memory, a magnetic disc device. The memory 100 stores in advance software component creation rules 60 and client program creation rules 80, and also stores the

25 software component definition data 50 during a system process. Further, the memory 100 stores the created software component module 70 and the client program

source code 90. The processing unit 10 is composed of

a CPU, and software running on the CPU. They provide

the three function sections of the software component

defining section 20, the automatic software component

5   creating section 30 and the automatic client program

creating section 40.

The software component defining section 20 is

a kind of an editor. The software component defining

section 20 provides a user interface in order that a

10 user defines various data necessary to create the

software components and the client program using the

same through the user input/output unit 200. The

software component defining section 20 acquires the

software component definition data 50 through an input

15 of data from a screen or an import of the data. The

acquired software component definition data 50 is

stored in the memory 100. Then, the automatic

software, component creating section 30 and the

automatic client program creating section 40 suitably

20 refers to it.

The client program creation rules 80 describe

rules when the client program is created on the basis

of the software component definition data 50.

Actually, the client program creation rules 80 firstly

25 describe a kind of definition data, and a manner of

creating the same. An actual value of the definition

data is acquired from the software component

definition data 50. For example, a certain rule

describes the execution of the definition of a

framework for a client program. A component name

required at that time is acquired from the software

5   component definition data 50. Similarly, other rules

describes the executions of the definitions with

regard to a parameter definition, a pre-process, a

component call process, and a post-process, and

specifies a method of defining each of them. The

10   actual values of a parameter name and a type necessary

to create them are acquired from the software

component definition data 50.

The client program creation rules 80 also

describe output data in relation to the definition

15   data and output positions or an output order. For

example, it is described in the process for setting a

value for a parameter created in the pre-process that

data should be outputted immediately before calling

the method containing its parameter. Also, it is

20   described in the process for acquiring a value from a

parameter created in the post-process that data is

outputted immediately after calling the method

containing the parameter.

It should be noted that the client program

25   creation rules 80 also describe output data having no

relation to the definition data and data with regard

to the output positions and the output order. For

example, there are an error process, a pre-process and a post-process that are carried out fixedly.

The software component creation rules 60 describe rules when a software component is created on
5 the basis of the software component definition data 50. Similarly to the client program creation rules 80, the software component creation rules 60 describe a kind of a definition data, a manner of creating the same, output data in relation to the definition data, the
10 output data or the output order, output data having no relation to the definition data and the output positions or the output order.

The automatic software component creating section 30 creates the software component module 70
15 based on the software component definition data 50 and the software component creation rules 60. The created software component module 70 is stored in the memory 100, in the case of the first embodiment.

The automatic client program creating section
20 40 creates the source code 90 of the client program using the software component created by the automatic software component creating section 30 based on the software component definition data 50 and the client program creation rules 80. The created source code 90
25 for the client program is stored in the memory 100 in the case of this embodiment.

Next, the respective units of the system for

automatically creating a program in this embodiment
will be described below in detail.

(1) Software Component Defining section 20

5   Typically, a plurality of software components
can exist in one software component module. Also, a
plurality of methods can exist in one software
component. Moreover, a plurality of parameters can
exist in one method. For this reason, definition data
10 necessary to create one software component module
typically have a hierarchical structure shown in Fig.
4. In short, one or more component data 52 exist in
association with one module data 51. One or more
method data 53 exist in association with each
15 component data 52. Moreover, one or more parameter
data 54 exist in association with each method data 53.

          The software component defining section 20
has three defining sections of a component data
defining section 21, a method data defining section 22
20 and a parameter data defining section 23, as shown in
Fig. 5, in correspondence to the hierarchical
structure. The component data defining section 21 is
used to define the data peculiar to the component
(module data 51 and component data 52) for each
25 software component included in the software component
module. The method data defining section 22 is used
to define the data peculiar to the method (method data

53) in association with the component data 52.

Moreover, the parameter data defining section 23 is

used to define the data peculiar to the parameter

(parameter data 54) in association with the method

5   data 53.

Here, in this embodiment, the respective

defining sections 21 to 23 are also used to define the

data necessary to create the client program, as well

as the software component module. In short, the

10   component data defining section 21 defines the

component data to include the data necessary to create

the client program. The method data defining section

22 defines the method data to include the data

necessary to create the client program. Moreover, the

15   parameter data defining section 23 defines the

parameter data to include the data necessary to create

the client program. Thus, the software component

definition data having the hierarchical structure

shown in Fig. 4 includes not only the data necessary

20   to create the software component but also the data

necessary to create the client program using the same.

Figs. 6A to 6D show examples of the data

included in the module data 51, the component data 52,

the method data 53 and the parameter data 54.

25   With reference to Fig. 6A, the module data 51

includes a module name 511 that is a name of a

software component module.

With reference to Fig. 6B, the component data
52 includes a component name 521 that is a name of a
software component, and a component attribute data 522
indicative of an initial value (default parameter) of
5   the component. As an example of the component
attribute data 522, there is connection data to a
mainframe. The connection data to the mainframe
includes, for example, the data listed below:
IP Address of Mainframe = 111.111.111.111;
10   Port Number of Mainframe = 8000;
Timeout Value at Transmission = 3; and
Timeout Value at Reception = 3.

     With reference to Fig. 6C, the method data 53
includes: a method name 531 that is a name of a
15   method; a method attribute data 532 indicative of a
method type, a type of a return value of a method; an
data 533 of a method call form indicative of a
transmission type, a reception type and a type of a
transmission/reception type; and a method call order
20   data 534 indicative of a necessary call order when
there are a plurality of methods. It should be noted
that as a method of defining the method call order
data 534, a method may be employed of explicitly
indicating the calling order of the self-methods in
25   each method data 53. Or, a method may be employed of
making an order of describing the plurality of method
data 53 in association with the component data 52

coincide with the calling order of the methods.

With reference to Fig. 6D, the parameter data 54 includes a parameter name 541 that is a name of a parameter, a parameter type 542, and a parameter

5   input/output type data 543. Desirably, the parameter name is defined as a name having a proper meaning. The parameter input/output type data 543 defines the parameter as any one among an input parameter, an output parameter, an input/output parameter and a no-

10 operation parameter.

(2) Automatic software Component Creating Section 30 And Software Component Creation Rules 60

The automatic software component creating section 30 is provided with a component creating

15 section 31, a method creating section 32, a parameter creating section 33 and a module creating section 34, as shown in Fig. 7. Also, the software component creation rules 60 are used when the automatic software component creating section 30 creates the software

20 component module 70 based on the software component definition data 50. As shown in Fig. 8, the software component creation rules 60 include component creation rules 61, method creation rules 62, parameter creation rules 63 and module creation rules 64. Moreover, the

25 component creation rules 61 contain property creation rules 611, initial value creation rules 612 and component framework creation rules 613, and the method

creation rules 62 contain method framework creation
rules 621 and method logic creation rules 622.

The parameter creating section 33 creates a
parameter portion by suitably referring to the
5   software component definition data 50 and the
parameter creation rules 63 in response to a parameter
creation request from the method creating section 32.

The method creating section 32 creates a
method portion by suitably referring to the software
10   component definition data 50 and the method creation
rules 62 in response to a method creation request from
the component creating section 31.

The component creating section 31 creates a
component portion by suitably referring to the
15   software component definition data 50 and the
component creation rules 61 in response to a component
creation request from the module creating section 32.

The module creating section 34 creates the
software component module 70 as a whole by suitably
20   referring to the software component definition data 50
and the module creation rules 64 and by suitably
calling the component creating section 31.

The functions of the module creating section
34, the component creating section 31, the method
25   creating section 32 and the parameter creating section
33 together with the content examples of the rules
will be described below in detail in the above-

mentioned order.

(2-1) Module Creating Section 34

Fig. 9 shows a processing example of the
module creating section 34. The module creating
section 34 firstly acquires the module name 511 in the
module data 51 and the component names 521 of all the
component data 52 associated with the module data 51
from the software component definition data 50 (S11).
Next, the module creating section 34 creates a project
file of a module in accordance with the acquired
module name 511, the acquired component name 521, and
a creation rule of the project file of the module
existing in the module creation rules 64 (S12). For
example, the following rule is described in advance in
the creation rule of the project file of the module.

[A component name of a project is set for a
portion of a component name in a template [Class =
Component Name; Component Name.cls], and a module name
of the project is set for a portion of a module name
in [Name = "Module Name", ExeName32 = "Module
Name.dll", and a project file is created].

In this case, it is supposed that the module
name 511 acquired at the step S11 is
ComponentModuleName, and three component names 521 are
"Component1", "Component2" and "Component3". At this
time, the following project file is created.

Class = Componet1; Component1.cls

Class = Componet1; Component1.cls

Class = Componet1; Component1.cls

Name="ComponentModuleName"

5   ExeName32="ComponentModuleName.dll"

Here, "Component1", "Component2" and "Component3" are the files of the components. "ComponentModuleName.dll" is the file of the software component module.

10   Next, the module creating section 34 calls the process for creating the components in the module of the component creating section 31 for the number of components (S13). The component name 521 is passed for each call. The component created in accordance

15   with the call is stored in the file of the component.

(2-2) Component Creating Section 31

Fig. 10 shows a processing example of the component creating section 31. When acquiring a

20   component name 521 from the module creating section 34 (S21), the component creating section 31 firstly creates the framework of the component in accordance with the component framework creation rules 613 (S23). This process is equivalent to the process for creating

25   a regular header corresponding to the acquired component name 521. The component framework creation rules 613 describe, for example, the following rule.

Thus, the framework of the component is created in accordance with this rule.

[An acquired component name is set for a portion of a component name of a template listed below.

5   VERSION 1.0 CLASS

BEGIN

        Multiple=-1'True

        Persistable=0'NotPersistable

        DataBindingBehavior=0'vbNone

10   DataSourceBehavior=0'vbNone

        MTSTansactionMode=0'NotAnMTSOb.ject

END

        Attribute VB-Name="ComponentName"

        Attribute VB-GlobalNameSpace=False

15   Attribute VB-GlobalNameSpace=False

        Attribute VB-Creatable=True

        Attribute VB-Exposed=True]

Next, the component creating section 31 acquires the component attribute data 52 of the

20   component from the software component definition data 50 (S23), and creates properties of the components for the number of acquired component attribute data in accordance with the property creation rules 611 (S24). Also, the component creating section 31 creates

25   initial values for the number of acquired component attribute data in accordance with the initial value creation rules 612 (S25).

As the property creation rules 611, the templates are provided for the respective types of the component attribute data, that can exist in the software component definition data 50, such as IP

5   address usage, port number usage and timeout usage. Each template has, for example, a form:

Public AAA As String

The component creating section 31 acquires the template corresponding to the name (AAA) of the

10 acquired component attribute data from the property creation rules 611, and thereby creates the property corresponding to each component attribute data and type. Thus, in the case of the acquisition of the component attribute data such as a connection

15 destination server name, an IP address of a mainframe, a port number of the mainframe, a timeout value in transmission and a timeout value in reception, the property corresponding to each of them is created.

Also, as the initial value creation rules 612,

20 for example, there is the following rule.

[A property name corresponding to each component attribute data and its value are set for the following position of a template AAA=BBB, as initial values in a form of PropertyName=Value.

25 Private Sub Class-Intialize()

AAA=BB

End Sub]

For example, the following process for creating initial values is created from such initial value creation rules 612 and the acquired component attribute data.

```
5   Private Sub Class-Intialize()

    MainFrameIP="111.111.111.111"

    MainFramePort=8000

    RcvTimeOut=3

    SndTimeOut=3

10  End Sub
```

Next, the component creating section 31 fetches the method names 531 in all the method data 53 associated with the component from the software component definition data 50, and then calls the method creating section 32 for the number of methods defined in the component (S26). The method name and the component name having its method are passed for each call.

20 (2-3) Method Creating Section 32

Fig. 11 shows a processing example of the method creating section 32. When acquiring a method name and a component name having its method from the component creating section 31 (S31), the method creating section 32 firstly creates the framework of the method in accordance with the software component definition data 50 and the method framework creation

rules 621 (S32). In the method framework creation

rules 621, for example, there is the following rule.

[A method parameter and its type and a type of a

return value are linked into a method name in a

5   following format and then outputted.

Public Function Method Name (All Method Parameters) As

Return Value Type

Method Process

End Function]

10   It should be noted that the process for

creating the method parameter calls the parameter

creating section 33. A parameter name, a method name

having its parameter and a component name having its

method are specified at a time of the call.

15   The following framework of a method is

created through the above-mentioned process, when it

is supposed that a method name is "Method1", a type of

a return value is "Long", and two method parameters

acquired by calling the parameter creating section 33

20 are "Param1 As Integer and Param2 As String".

Public Function Method1 (Param1 As Integer, Param2 As

String) As Long

Method Process

End Function

25   Next, the method creating section 32 creates

the method process in accordance with the software

component definition data 50 and the method logic

creation rules 622 (S33). In a case of the method

having a function to access to a mainframe, the

created method process is a communication process with

the mainframe. Since a template describing a

5   communication process complying with an external

interface of the mainframe is provided in the method

logic creation rules 622 for each method and each

method call type, the template corresponding to the

method call type is selected, and a parameter name is

10   set for the template. Thus, the method process is

created. The creation of the data depending on the

parameter is repeated for the number of parameters.

The data peculiar to the method is created only once.

The examples of the transmission type, the reception

15   type and the transmission/reception type are as

follows:

· Transmission Type

Public Sub Method1 (...Parameter...)

   WbRet =Send (...Parameter...)

20   End

· Reception Type

Public Sub Method2 (...Parameter...)

   WbRet =Recv (...Parameter...)

End

25   · Transmission/Reception Type

Public Sub Method3 (...Parameter...)

   WbRet =Send (...Parameter...)

```
WbRet =Recv (...Parameter...)
End
```

(2-4) Parameter Creating Section 33

Fig. 12 shows a processing example of the parameter creating section 33. When acquiring a parameter name, a method name to which it belongs and a component name from the method creating section 32 (S41), the parameter creating section 33 acquires the component data and the parameter type 542 associated with the method data from the software component definition data 50, and then creates a method parameter in accordance with the parameter creation rules 63 (S42).

A rule indicating that a parameter name and its type are linked through "As" to then create a method parameter is provided in the parameter creation rules 63. Thus, if the parameter name is assumed to be "Pram1" and its type is assumed to be "String", the following method parameter is returned back to the method creating section 32 as a call source.
Param1 As String

(3) Automatic Client Program Creating Section 40 And Client Program Creation Rules 80

The automatic client program creating section 40 is composed of a definition data extracting section

41, a client module creating section 42, a parameter

definition creating section 43, a pre-process creating

section 44, a component call creating section 45 and a

post-process creating section 46, as shown in Fig. 13.

5 Also, the client program creation rules 80 are a set

of the various rules to be used when the automatic

client program creating section 40 creates the source

code 90 of the client program based on the software

component definition data 50. As shown in Fig. 14,

10 the client program creation rules 80 includes client

module creation rules 81, parameter definition

creation rules 82, pre-process creation rules 83,

component call creation rules 83 and post-process

creation rules 85. Moreover, the client module

15 creation rules 81 contain client program framework

creation rules 811 and project file creation rules 812

of a module, and the pre-process creation rules 83

contain component declaration creation rules 831 and

input parameter setting process creation rules 832.

20   The definition data extracting section 41

extracts the definition data required by the

respective sections 42 to 46 from the software

component definition data 50.

          The client module creating section 42

25 suitably refers to the software component definition

data 50 and the client module creation rules 81 and

also suitably calls the parameter definition creating

section 43, the pre-process creating section 44, the component call creating section 45 and the post-process creating section 46 and then creates the entire framework of the source code 90 of the client

5   program.

The parameter definition creating section 43 suitably refers to the software component definition data 50 and the parameter definition creation rules 82 in response to a parameter definition creation request

10 from the client module creating section 42, and then creates the declaration and definition of a parameter corresponding to a method called from the client program.

The pre-process creating section 44 suitably

15 refers to the software component definition data 50 and the pre-process creation rules 83 in response to a pre-process creation request from the client module creating section 42, and then creates a pre-process, which needs to be executed prior to a call of a

20 software component, such as a process of setting of a value for a property or a parameter that must be executed prior to a call of a method. Another initializing process fixedly necessary is created here.

The component call creating section 45

25 suitably refers to the software component definition data 50 and the component call creation rules 84 in response to a component call creation request from the

client module creating section 42, and then creates a portion of calling a method of a software component.

The post-process creating section 46 suitably refers to the software component definition data 50

5 and the post-process creation rules 85 in response to a post-process creation request from the client module creating section 42, and then creates a post-process, which needs to be executed after a call of a software component, such as a process of acquiring a value of a

10 parameter that must be executed after a call of a method. An error process and another initializing process fixedly necessary are created here.

The functions of the client module creating section 42, the parameter definition creating section

15 43, the pre-process creating section 44, the component call creating section 45 and the post-process creating section 46 will be described below in detail in the above-mentioned order together with the content examples of the rules.

20

(3-1) Client Module Creating Section 42 And Client Module Creation Rules 81

Fig. 15 shows a processing example of the client module creating section 42. The client module

25 creating section 42 firstly acquires the component names 521 in all the component data 52 associated with the module data 51 from the software component

definition data 50 by the definition data extracting

section 41. Then, the client module creating section

42 creates the framework of a client program

corresponding to each component based on the acquired

5 component names 521 and the client program framework

creation rules (S51). For example, the following rule

is described in advance in the client program

framework creation rules 811.

[An acquired component name is set for the following

10 section of a component name of a template, and a

framework of a client is created].

```
Dim Component Name As Object

Public Sub Main()

End Sub ]
```

15   Thus, the frameworks of the following three

client programs are created if it is supposed that the

acquired component names are "Component1",

"Component2" and "Component3".

1) Framework of Client Program Corresponding to

20 "Component1"

```
Dim Component1 As Object

Public Sub Main()

End Sub
```

2) Framework of Client Program Corresponding to

25 "Component2"

```
Dim Component2 As Object

Public Sub Main()
```

End Sub

3) Framework of Client Program Corresponding to
"Component3"

Dim Component3 As Object

5   Public Sub Main()

End Sub

       Then, the client module creating section 42
suitably refers to the software component definition
data 50 by the definition data extracting section 41
10 for each component, and calls the parameter defining
section 43, the pre-process creating section 44, the
component call creating section 45 and the post-
process creating section 46. Then, the client module
creating section 42 creates each program for the
15 parameter definition, the pre-process, the component
call and the post-process in each proper section (in
short, a section complying with an output position or
an output order of each data specified in the rule)
within the framework created for each component, and
20 then creates the program for calling the component
(S52).

       Next, the client module creating section 42
creates a project file (userapp.vbp) that describes
names of components of a project in accordance with
25 the software component definition data 50 and the
project file creation rules 812 of the module (S53).

       A template for a project file is provided in

the project file creation rules 812 of the module.

Thus, the client module creating section 42 can create

the project file by setting a component name for the

template. For example, it is supposed that there are

5   three component names of "Component1", "Component2"

and "Component3". In this case, the project file is

created which has the following content:

Module=Component1; Component1.bas;

Module=Component2; Component2.bas; and

10   Module=Component3;Component3.bas.

(3-2) Parameter Definition Creating Section 43 And

Parameter Definition Creation Rules 82

        Fig. 16 shows a processing example of the

15   parameter definition creating section 43. When the

client module creating section 42 is called from the

client module creating section 42 by specifying a

component name, the parameter definition creating

section 43 acquires all parameter names 541 in all the

20   method data 53 associated with the component data 52

corresponding to the component name and their types

542, from the software component definition data 50

through the definition data extracting section 41

(S61). Then, the parameter definition creating

25   section 43 creates the parameter definition in

accordance with the parameter definition creation rule

82 (S62).

In the parameter definition creation rule 82, a rule is provided in which the parameter name 541 and its type 542 are linked through "As" after "Dim" to create the parameter definition. Thus, when it is

5 supposed that there are three parameter names 541 of "Pram1", "Pram2" and "Param3" and that their types 542 are "String", "Integer" and "Long", the following parameter definition is created.

Dim Param1 As String

10 Dim Param2 As Integer

Dim Param3 As Long

(3-3) Pre-Process Creating Section 44 And Pre-Process Creation Rules 83

15 Fig. 17 shows a processing example of the pre-process creating section 44. When the pre-process creating section 44 is called from the client module creating section 42 by specifying a module name and a component name, the pre-process creating section 44

20 creates a declaration of a component in accordance with the component declaration creation rules 831 (S71). For example, the following rule is provided in advance in the component declaration creation rule 831. [A module name and a component name are set for the

25 following sections of a module name and a component name of a template, and a declaration of a component is created.

```
Dim Component Name As Object

Set Component Name = CreateObject

("ModuleName.ComponentName")]
```

Thus, when it is supposed that a module name

5   is "Module1" and a component name is "Component1", the

following component declaration is created:

```
Dim Component1 As Object

Set Component1=CreateObject ("Module.Component1")
```

Next, the pre-process creating section 44

10 refers to the parameter data 54 associated with the

method data 53 associated with the module name and the

component name, from the software component definition

data 50 through the definition data extracting section

41. Then, the pre-process creating section 44 creates

15 a setting process for a parameter serving as an input

(an input parameter and an input/output parameter) in

accordance with the input parameter setting process

creation rules 832 (S72). Actually, the pre-process

creating section 44 refers to the parameter

20 input/output type data 543 for each parameter name 541

in the parameter data 54, and extracts only the

parameter name 541 responsible for the input parameter

or the input/output parameter. Then, the pre-process

creating section 44 creates the setting process for

25 the input parameter in accordance with the input

parameter setting process creation rules 832. For

example, the following rule is provided in advance in

the input parameter setting process creation rule 832.

[A parameter name is set for a following section of a

parameter name of a template, and a setting process

for an input parameter is created.

5   Parameter Name = ?]

         Thus, when it is supposed that "Param1",

"Param2" and "Param3" are input or input/output

parameter names, the following input parameter setting

process is created.

10   Param1=?

     Param2=?

     Param3=?

     (3-4) Component Call Creating Section 45 And Component

15   Call Creation Rules 84

         Fig. 18 shows a processing example of the

component call creating section 45. When the

component call creating section 45 is called from the

client module creating section 42 by specifying a

20   module name and a component name, the component call

creating section 45 acquires from the software

component definition data 50 through the definition

data extracting section 41, method names in all the

method data 53 associated with the component data 52

25   having the specified module name and the specified

component name, and the method call order data 534,

and all parameter names 541 associated with each

method data 53. Then, the component call creating

section 45 creates a component call for calling each

method specified by the call order data 534, in

accordance with the component call creation rules 84

5 (S81). For example, the following rule for each of

method call types is provided in advance in the

component call creation rule 84.

[Each name is set for the following sections of a

component name, a method name and a parameter name of

10 a template, and a component call process is created.

Call Component Name, Method Name, Parameter Name]

Thus, when it is supposed that a component

name is "ComponentName", there are four method names

of "Bind", "Send", "Recv" and "Unbind", there are

15 "Param1" and "Param2" as "Send" parameters, there are

"Param3" and "Param4" as "Recv" parameters, and a

method call order specified by the call order data 534

is an order of "Bind", "Send", "Recv" and "UnBind".

For example, the following component call process is

20 created.

Call ComponentName.Bind()

Call ComponentName.Send(Param1,Param2)

Call ComponentName.Recv(Param3, Param4)

Call ComponentName.UnBind()

25 It should be noted that the setting process

for the value created by the pre-process creating

section 44 for the parameter serving as the input

within "Param1" and "Param2" is assembled immediately

before "Call ComponentName.Send (Param1, Param2)", and

the acquiring process for the value created by the

post-process creating section 46 for the parameter

5   serving as the output within "Param3" and "Param4" is

assembled immediately after it. Also, the setting

process for the value created by the pre-process

creating section 44 for the parameter serving as the

input within "Param3" and the "Param4" is assembled

10   immediately before "Call ComponentName.Recv

(Param3,Param4)", and the acquiring process for the

value created by the post-process creating section 46

for the parameter serving as the output within

"Param3" and "Param4" is assembled immediately after

15   it.

(3-5) Post-Process Creating Section 46 And Post-

Process Creation Rules 85

        Fig. 19 shows a processing example of the

20   post-process creating section 46. When the post-

process creating section 46 is called by specifying a

module name and a component name from the client

module creating section 42, the post-process creating

section 46 refers through the definition data

25   extracting section 41, to the parameter data 54

associated with the method data 53 which is associated

with the module name and the component name. Then,

the post-process creating section 46 creates the

acquiring process for the value from the parameter

serving as the output (the output parameter and the

input/output parameter) in accordance with an output

5   parameter setting process creation rule (not shown) in

the post-process creation rules 85. Actually, the

post-process creating section 46 refers to the

parameter input/output type data 543 for each

parameter name 541 in the parameter data 54, and

10 extracts only the parameter name 541 serving as the

output parameter or the input/output parameter. Then,

the post-process creating section 46 creates the

acquiring process for the value of the output

parameter in accordance with the output parameter

15 setting process creation rule. For example, the

following rule is provided in advance in the output

parameter setting creation rules in the post-process

creation rules 85.

[A parameter name is set for the following section of

20 a parameter name of a template, and an acquiring

process for a value of an output parameter is created.

?=Parameter Name]

Thus, when it is supposed that "Param1",

"Param2" and "Param3" are output or input/output

25 parameter names, the following input parameter setting

process is created.

?=Param1

?=Param2

?=Param3

It should be noted that another embodiment
may be considered so as to separately include the
5   definition data necessary to create the software
component and the definition data necessary to create
the client program. In such a case, the two
definition units are required, and the definition of a
user needs to be carried out two times. Also, the
10   creation operations need to be carried out separately
from each other. On the contrary, in the above-
mentioned embodiment, the automatic client program
creating section 40 and the automatic software
component creating section 30 use the common
15   definition data 50. Thus, the definition unit is
sufficient to have only one interface and an operation
of the user is sufficient to be carried out once.

In the system for automatically creating a
software component according to the present invention,
20   the software component defining section, in addition
to data necessary to create a software component,
receives even data necessary to create a client
program using the software components from the user
input/output unit, and creates the software component
25   definition data. The automatic software component
creating section creates the software components based
on the software component definition data. On the

other hand, the automatic client program creating

section creates a source code of the client program

based on the software component definition data. At

this time, the component call creating section within

5   the automatic client program creating section refers

to an data about an order of calling methods in the

software component corresponding to messages given to

a transaction process program, in a one-to-one

relationship, from the software component definition

10 data, and creates a description of a part of calling

the methods in the client program. Accordingly, it is

not necessary for a developer of the client program

itself to describe the part of calling the methods.

Also, it is not necessary to inquire of a technician

15 of a mainframe about the order of calling the methods.

        If the data necessary to create the client

program includes the data about a parameter

input/output type specified by a message given to the

transaction process program, the pre-process creating

20 section within the automatic client program creating

section refers to the data about the parameter

input/output type, and describes a process for setting

a value for the parameter before calling a method

having an input parameter. The post-process creating

25 section refers to the data about the parameter

input/output type, and describes a process for

acquiring a value of the parameter after calling a

method having an output parameter. In the description

of the process for setting the value for the parameter,

which is described by the pre-process creating section,

an input source of the value is unknown when a source

5   code of the client program is created. Thus, a

predetermined symbol (for example, [?]) indicative of

the unknown fact is used to create as a description,

for example, such as [Parameter Name = ?]. Therefore,

the developer of the client program can easily

10   understand what kind of data is outputted when a

certain data is inputted. It should be noted that the

data of a place serving as an actual input source and

an actual output destination (for example, the data

about an input column and an output column on a GUI

15   screen designed by the developer of the client

program) is manually set for the portion [?].

As mentioned above, according to the present

invention, in addition to the data necessary to create

the software component, the definition data including

20   even the data necessary to create the client program

using the software component is inputted and stored as

the software component definition data. Then, the

source code of the client program is automatically

created in accordance with this definition data. Thus,

25   even the person having no knowledge of the mainframe

can develop the client program using the software

components to access to the mainframe. Moreover, most

portions of the source code in the client program such as the typical portion can be automatically created. Therefore, it is possible to largely reduce the burden on the developer of the client program.
